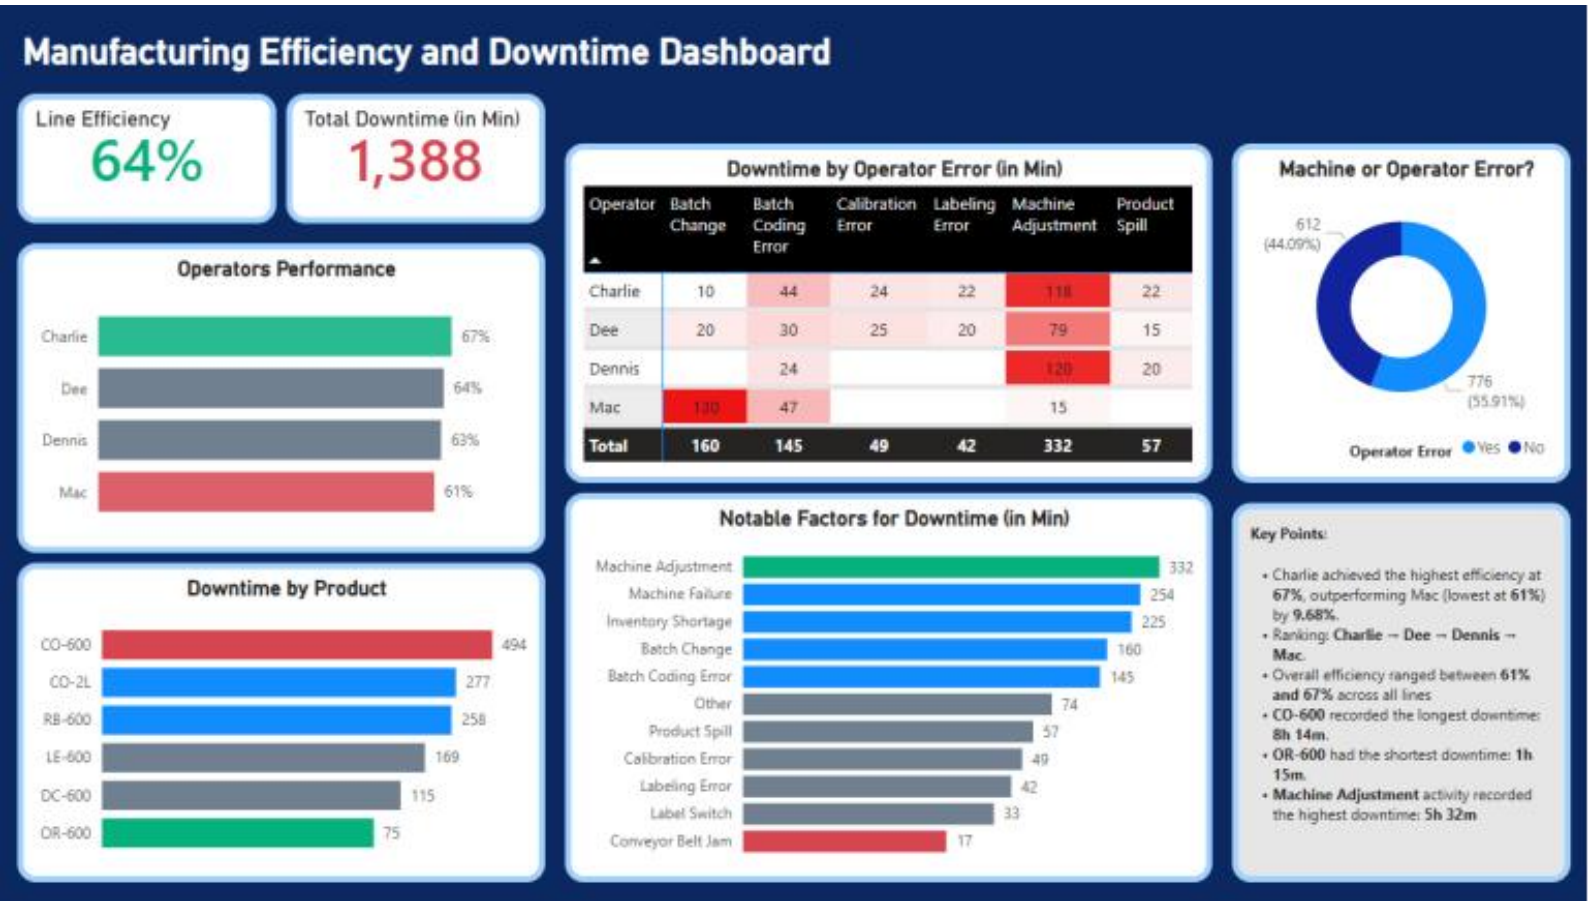
Soda bottling production line



Insights

Efficiency & Operator Performance

Line efficiency is low at 64%, leaving room for improvement that can be through operator training, with Charlie leading at 67% and Mac trailing at 61%, It might help to give extra coaching to get him back on track and close the small but consistent performance gap.

Operator Error Breakdown

Mac accounts for the majority of batch change errors (130), with over 80%, while Dennis (120) and Charlie (118) drive most machine adjustment downtime, with Charlie also leading in batch coding errors (44) and Dee showing a more balanced error distribution.

Product Impact

CO-600 experiences the longest downtime at 494 minutes, making it the most problematic line, while OR-600 shows greater stability with only 75 minutes of downtime.

Process Improvement Recommendations

Structured Operator Training

Deploy a formal training program to raise overall line efficiency that is currently at 64%, focusing on consistent execution of key processes.

Targeted Coaching for Mac

Provide one-on-one coaching to address Mac's performance gap and reduce his disproportionately high batch change errors, helping close the spread between operators.

Error-Proofing Measures

Introduce practical tools such as checklists, digital prompts, or automated validations to reduce operator mistakes and improve reliability.

Standardization of Machine Adjustments

Review and standardize machine adjustment procedures to minimize downtime, with potential exploration of semi-automation for consistency.

Root Cause Analysis for CO-600

Prioritize CO-600 for detailed investigation as it appears to be the most problematic line, and apply lessons from the more stable OR-600 to improve overall reliability
